

Having thus described the preferred embodiment, the invention is now claimed to be:

1. A system for microbially decontaminating a device, the system including:
 - a cabinet which defines an interior chamber for receiving the device;
 - 5 spray nozzles, disposed within the chamber, for spraying a decontaminant fluid over an external surface of the device;
 - a support which supports the device within the chamber;
 - an activation system which displaces at least a portion of the support for changing points of contact between the
 - 10 device and the support.
2. The system of claim 1, wherein the support is supported adjacent an upper end for pivotal movement and wherein the activation system includes a means for periodically pivoting support.
3. The system of claim 2, wherein the support includes a rack and further including a hanger in the chamber on which the rack is removably and pivotally hung.
4. The system of claim 2, wherein the support is supported on at least one hook on a wall of the chamber.
5. The system of claim 1, wherein the activation system includes a piston assembly.
6. The system of claim 5, further including:
 - a pneumatic system which provides motive power to the piston assembly.
7. The system of claim 5, wherein the piston assembly includes:
 - a piston body portion;

10776286-520701

a shaft extending from the piston body portion and
5 intermittently engaging the support when the piston assembly
is activated; and

a piston cylinder in which the piston body portion is
slidably received.

8. The system of claim 1, wherein the nozzles and the
device are positioned within the chamber such that the
external surface of the device is impacted with a spray from
at least one nozzle at an angle of no more than 45 degrees
5 from perpendicular to the external surface.

9. The system of claim 1, wherein the support includes
pegs which position the device such that flexible portions of
the device are bent into an arc with a minimum radius of no
less than 15 centimeters.

10. The system of claim 1, further including:

a clip which releasably couples a tip portion of the
device to one of the support and another portion of the
device, to keep the tip portion securely positioned.

11. The system of claim 10, wherein the clip includes
at least one upper finger and at least one lower finger, the
fingers each contacting the device at a ridge to minimize
contact between the clip and the device.

12. A system for cleaning and microbially
decontaminating endoscopes, the system comprising:

a cabinet defining a vertically elongated chamber having
rear and side walls and a front door;

5 spray nozzles mounted on at least the rear and side
walls of the chamber for spraying liquid cleaning and
microbially decontaminating solutions;

a hanger on the chamber rear wall;

a rack configured to support a coiled endoscope, the
10 rack being pivotally and removably hung on the hanger; and

55776266-000701
a reciprocating drive having a drive member extending from the chamber rear wall adjacent the rack such that as the drive member reciprocates it engages and pushes the rack to pivot on the hanger and disengages from the rack to permit 15 the liquid cleaning and decontaminating solutions to contact engaging surfaces of the rack and the drive member.

13. A method of microbially decontaminating a device comprising:

- (a) mounting the device on a support;
- (b) spraying a microbial decontaminant solution over the 5 device to microbially decontaminate the exterior surfaces of the device; and
- (c) during at least step (b), agitating the support to change points of contact between the device and the support.

14. The method of claim 13, wherein the step of agitating the support includes:

striking the support at intervals such that the support pivots around a pivot point.

15. The method of claim 14, wherein the support is struck at least once every 10 seconds.

16. The method of claim 13, wherein the step of agitating the support includes:

- at intervals of time, driving a piston between first and second positions such that a shaft connected with the piston 5 strikes the support.

17. The method of claim 16, wherein the step of driving the piston includes pneumatically driving the piston.

18. The method of claim 13, further including:

supporting the support in a chamber such that the support is free to pivot when agitated.

19. The method of claim 13, wherein the step of spraying a microbial decontaminant solution includes alternating spraying from different directions to change points of contact between the support and the device.

20. The method of claim 13, wherein a first set of the spray nozzles sprays the decontaminant solution for a first period of time and then a second set of the spray nozzles sprays the decontaminant solution for a second period of
5 time.
